Docket No. 14729

UNITED STATES PATENT AND TRADEMARK OFFICE
VERIFICATION OF A TRANSLATION

I, the below named translator, hereby declare that:

My name and post office address are as stated below;

That I am knowledgeable in the English language and in the Japanese language, and that I believe the attached English translation of the Japanese Patent Application Serial No.: 2000-198059 is true and complete.

I hereby declare that all statements made herein of my own knowledge are true and that all statements made on information and belief are believed to be true; and further that these statements were made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under Section 1001 of Title 18 of the United States Code and that such willful false statements may jeopardize the validity of the application or any patent issued thereon.

Date: August 18, 2004

Full name of the translator: MAKOTO YANAGAWA

[TITLE OF THE INVENTION]

TRANSMISSION POWER CONTROL SYSTEM, CONTROL METHOD,

5 BASE STATION, CONTROL STATION AND STORAGE MEDIUM

[CLAIM FOR PATENT]

[CLAIM 1]

A transmission power control system in a cellular communication system including a plurality of cells, a plurality of base stations respectively arranged in
10 respective of said plurality of cells, mobile stations moving within said cells, and control station provided in common for said plurality of base stations and transmitting control instruction for balance adjustment of transmission power
15 to respective of said mobile stations from said base stations,

wherein said base station comprising control means for controlling initiation of a balance adjustment period for performing said balance adjustment from a frame number determined on the basis of frame number of the balance
20 adjustment period.

[CLAIM 2]

A transmission power control system as set forth in claim 1, wherein assuming that a frame number of transmission frame to said mobile station is CFN and said balance
25 adjustment period is Nperiod frame, said control means is responsive to reception of said control instruction to perform initiation control of said balance adjustment period

from the frame of the frame number CFN to be mod $(CFN, m \times N_{period}) = L$ (wherein, m is natural number, L is 0 or natural number smaller than $m \times N_{period}$ common to all base stations).

[CLAIM 3]

5 A transmission power control system as set forth in claim 1, wherein assuming that a frame number of transmission frame to said mobile station is CFN and said balance adjustment period is N_{period} frame, said control means is responsive to reception of said control instruction to
10 perform initiation control of said balance adjustment period from a frame where a number at the first digit as expressing said CFN by $m \times N_{period}$ base number (wherein, m is natural number) becomes a predetermined value.

[CLAIM 4]

15 A transmission power control system as set forth in claim 1, wherein assuming that a frame number of transmission frame to said mobile station is CFN and said balance adjustment period is N_{period} frame, said control means is responsive to reception of said control instruction to
20 perform initiation control of said balance adjustment period from a frame where said CFN becomes $m \times N_{period} + L$ (wherein m is 0 or natural number and L is 0 or natural number common to all base stations).

[CLAIM 5]

25 A transmission power control system as set forth in claim 4, wherein said m is natural number and said L is 0.

[CLAIM 6]

A transmission power control system as set forth in claim 1, wherein said control means resumes said balance adjustment period from a frame defined by the same rule as a rule determining initiation of the balance adjustment period when said frame number is varied from the maximum value to a minimum value or from the minimum value to the maximum value in discontinuous manner.

[CLAIM 7]

A transmission power control system as set forth in claim 4, wherein assuming that a frame number of transmission frame to said mobile station is CFN and said balance adjustment period is Nperiod frame, said control means resumes said balance adjustment period from a frame to be $m \times Nperiod + L$ when said frame number is varied from the maximum value to a minimum value or from the minimum value to the maximum value in discontinuous manner.

[CLAIM 8]

A transmission power control system as set forth in claim 1, wherein said control station includes means for selecting said Nperiod as a value satisfying a relationship of $k \times Nperiod = CFNmax$ (k is integer) assuming that a frame number of transmission frame to said mobile station is CFN, said balance adjustment period is Nperiod frame, minimum value of said CFN is 1, maximum value is CFNmax or minimum value is 0 and maximum value is $CFNmax - 1$, and

control means of each of said base station initiate control of said balance adjustment period from a frame to

be $m \times N_{\text{period}} + L$ (wherein m is 0 or natural number and L is 0 or natural number common to all base stations).

[CLAIM 9]

A transmission power control system as set forth in
5 claim 1, wherein assuming that a frame number of transmission
frame to said mobile station is CFN, said balance adjustment
period is N_{period} frame, said control means selects said
 N_{period} as a value satisfying a relationship of $k \times N_{\text{period}}$
= CFNmax (k is integer) when minimum value of said CFN is
10 1, maximum value is CFNmax or minimum value is 0 and maximum
value is CFNmax - 1, to initiate control of said balance
adjustment period from a frame to be $m \times N_{\text{period}} + L$ (wherein
 m is 0 or natural number and L is 0 or natural number common
to all base stations).

15 [CLAIM 10]

A transmission power control system as set forth in
one of claims 1 to 9, wherein said control means sets an
adjustment amount in said balance adjustment at a value of
predetermined ratio to a difference between said
20 transmission power upon initiation of said balance
adjustment period and a reference value.

[CLAIM 11]

A transmission power control method in a cellular
communication system including a plurality of cells, a
25 plurality of base stations respectively arranged in
respective of said plurality of cells, mobile stations moving
within said cells, and control station provided in common

for said plurality of base stations and transmitting control instruction for balance adjustment of transmission power to respective of said mobile stations from said base stations,

wherein said method comprising a control step of
5 controlling initiation of a balance adjustment period for performing said balance adjustment from a frame number determined on the basis of frame number of the balance adjustment period, in each base station.

[CLAIM 12]

10 A transmission power control method as set forth in claim 11, wherein assuming that a frame number of transmission frame to said mobile station is CFN and said balance adjustment period is Nperiod frame, said control step includes a step of initiating control of said balance
15 adjustment period from the frame of the frame number CFN to be $\text{mod}(\text{CFN}, m \times \text{Nperiod}) = L$ (wherein, m is natural number, L is or natural number smaller than $m \times \text{Nperiod}$ common to all base stations) in response to reception of said control instruction.

20 [CLAIM 13]

A transmission power control method as set forth in claim 11, wherein assuming that a frame number of transmission frame to said mobile station is CFN and said balance adjustment period is Nperiod frame, said control step is
25 responsive to reception of said control instruction to perform initiation control of said balance adjustment period from a frame where a number at the first digit as expressing

said CFN by $m \times N_{\text{period}}$ base number (wherein, m is natural number) becomes a predetermined value.

[CLAIM 14]

A transmission power control method as set forth in
5 claim 11, wherein assuming that a frame number of transmission
frame to said mobile station is CFN and said balance
adjustment period is N_{period} frame, said control step
includes a step responsive to reception of said control
instruction to perform initiation control of said balance
10 adjustment period from a frame where said CFN becomes $m \times$
 $N_{\text{period}} + L$ (wherein m is 0 or natural number and L is 0
or natural number common to all base stations.

[CLAIM 15]

A transmission power control method as set forth in
15 claim 14, wherein said m is natural number and said L is
0.

[CLAIM 16]

A transmission power control method as set forth in
claim 11, wherein said control step resumes said balance
20 adjustment period from a frame defined by the same rule as
a rule determining initiation of the balance adjustment
period when said frame number is varied from the maximum
value to a minimum value or from the minimum value to the
maximum value in discontinuous manner.

25 [CLAIM 17]

A transmission power control method as set forth in
claim 14, wherein assuming that a frame number of transmission

frame to said mobile station is CFN and said balance
adjustment period is $N_{\text{period}} \text{ frame}$, said control step resumes
said balance adjustment period from a frame to be $m \times N_{\text{period}}$
+ L when said frame number is varied from the maximum value
5 to a minimum value or from the minimum value to the maximum
value in discontinuous manner.

[CLAIM 18]

A transmission power control method as set forth in
claim 11, wherein said control station performs a step of
10 selecting said N_{period} as a value satisfying a relationship
of $k \times N_{\text{period}} = \text{CFN}_{\text{max}}$ (k is integer) assuming that a frame
number of transmission frame to said mobile station is CFN,
said balance adjustment period is $N_{\text{period}} \text{ frame}$, minimum
value of said CFN is 1, maximum value is CFN_{max} or minimum
15 value is 0 and maximum value is $\text{CFN}_{\text{max}} - 1$, and

control step in each of said base station initiate
control of said balance adjustment period from a frame to
be $m \times N_{\text{period}} + L$ (wherein m is 0 or natural number and
L is 0 or natural number common to all base stations).

20 [CLAIM 19]

A transmission power control method as set forth in
claim 11, wherein assuming that a frame number of transmission
frame to said mobile station is CFN, said balance adjustment
period is $N_{\text{period}} \text{ frame}$, said control step selects said
25 N_{period} as a value satisfying a relationship of $k \times N_{\text{period}}$
= CFN_{max} (k is integer) when minimum value of said CFN is
1, maximum value is CFN_{max} or minimum value is 0 and maximum

value is $CFN_{max} - 1$, to initiate control of said balance adjustment period from a frame to be $m \times N_{period} + L$ (wherein m is 0 or natural number and L is 0 or natural number common to all base stations).

5 [CLAIM 20]

 A transmission power control method as set forth in one of claims 11 to 19, wherein said control step sets an adjustment amount in said balance adjustment at a value of predetermined ratio to a difference between said
10 transmission power upon initiation of said balance adjustment period and a reference value.

 [CLAIM 21]

 A base station in a cellular communication system including a plurality of cells, a plurality of said base
15 stations respectively arranged in respective of said plurality of cells, mobile stations moving within said cells, and control station provided in common for said plurality of base stations and transmitting control instruction for balance adjustment of transmission power to respective of
20 said mobile stations from said base stations, said base station comprising:

 control means for controlling initiation of a balance adjustment period for performing said balance adjustment from a frame number determined on the basis of frame number
25 of the balance adjustment period.

 [CLAIM 22]

 A base station as set forth in claim 21, wherein

assuming that a frame number of transmission frame to said mobile station is CFN and said balance adjustment period is Nperiod frame, said control means initiation control of said balance adjustment period from the frame of the frame number CFN to be $\text{mod}(\text{CFN}, m \times \text{Nperiod}) = L$ (wherein, m is natural number, L is or natural number smaller than $m \times \text{Nperiod}$ common to all base stations) in response to reception of said control instruction.

[CLAIM 23]

10 A base station as set forth in claim 21, wherein assuming that a frame number of transmission frame to said mobile station is CFN and said balance adjustment period is Nperiod frame, said control means is responsive to reception of said control instruction to perform initiation control of said balance adjustment period from a frame where a number at the first digit as expressing said CFN by $m \times \text{Nperiod}$ base number (wherein, m is natural number) becomes a predetermined value.

[CLAIM 24]

20 A base station as set forth in claim 21, wherein assuming that a frame number of transmission frame to said mobile station is CFN and said balance adjustment period is Nperiod frame, said control means is responsive to reception of said control instruction to perform initiation control of said balance adjustment period from a frame where said CFN becomes $m \times \text{Nperiod} + L$ (wherein m is 0 or natural number and L is 0 or natural number common to all base stations).

[CLAIM 25]

A base station as set forth in claim 24, wherein said m is natural number and said L is 0.

[CLAIM 26]

5 A base station as set forth in claim 21, wherein said control means resumes said balance adjustment period from a frame defined by the same rule as a rule determining initiation of the balance adjustment period when said frame number is varied from the maximum value to a minimum value
10 or from the minimum value to the maximum value in discontinuous manner.

[CLAIM 27]

A base station as set forth in claim 24, wherein assuming that a frame number of transmission frame to said
15 mobile station is CFN and said balance adjustment period is Nperiod frame, said control means resumes said balance adjustment period from a frame to be $m \times Nperiod + L$ when said frame number is varied from the maximum value to a minimum value or from the minimum value to the maximum value in
20 discontinuous manner.

[CLAIM 28]

A base station as set forth in claim 21, wherein assuming that a frame number of transmission frame to said mobile station is CFN, said balance adjustment period is
25 Nperiod frame, said control means selects said Nperiod as a value satisfying a relationship of $k \times Nperiod = CFN_{max}$ (k is integer) when minimum value of said CFN is 1, maximum

value is CFNmax or minimum value is 0 and maximum value is CFNmax - 1, to initiate control of said balance adjustment period from a frame to be $m \times N_{\text{period}} + L$ (wherein m is 0 or natural number and L is 0 or natural number common to
5 all base stations).

[CLAIM 29]

A base station as set forth in one of claims 21 to 28, wherein said control means sets an adjustment amount in said balance adjustment at a value of predetermined ratio
10 to a difference between said transmission power upon initiation of said balance adjustment period and a reference value.

[CLAIM 30]

A control station in a cellular communication system
15 including a plurality of cells, a plurality of base stations respectively arranged in respective of said plurality of cells, mobile stations moving within said cells, and control station provided in common for said plurality of base stations and transmitting control instruction for balance adjustment
20 of transmission power to respective of said mobile stations from said base stations, each of said base station initiate control of a balance adjustment period from a frame to be $m \times N_{\text{period}} + L$ (wherein m is 0 or natural number and L is 0 or natural number common to all base stations, N_{period}
25 is a period for performing said balance adjustment).

said control station comprising means for selecting said N_{period} as a value satisfying a relationship of $k \times$

Nperiod = CFNmax (k is integer) assuming that a frame number of transmission frame to said mobile station is CFN, said balance adjustment period is Nperiod frame, minimum value of said CFN is 1, maximum value is CFNmax or minimum value is 0 and maximum value is CFNmax - 1.

[CLAIM 31]

A storage medium storing a control program for a transmission power control method in a cellular communication system including a plurality of cells, a plurality of base stations respectively arranged in respective of said plurality of cells, mobile stations moving within said cells, and control station provided in common for said plurality of base stations and transmitting control instruction for balance adjustment of transmission power to respective of said mobile stations from said base stations,

wherein said control program comprising a control step of controlling initiation of a balance adjustment period for performing said balance adjustment from a frame number determined on the basis of frame number of the balance adjustment period, in each base station.

[CLAIM 32]

A storage medium as set forth in claim 31, wherein assuming that a frame number of transmission frame to said mobile station is CFN and said balance adjustment period is Nperiod frame, said control step includes a step of initiating control of said balance adjustment period from the frame of the frame number CFN to be mod (CFN, m x Nperiod)

= L (wherein, m is natural number, L is or natural number smaller than $m \times N_{\text{period}}$ common to all base stations) in response to reception of said control instruction.

[CLAIM 33]

5 A storage medium as set forth in claim 31, wherein assuming that a frame number of transmission frame to said mobile station is CFN and said balance adjustment period is $N_{\text{periodframe}}$, said control step is responsive to reception of said control instruction to perform initiation control
10 of said balance adjustment period from a frame where a number at the first digit as expressing said CFN by $m \times N_{\text{period}}$ base number (wherein, m is natural number) becomes a predetermined value.

[CLAIM 34]

15 A storage medium as set forth in claim 31, wherein assuming that a frame number of transmission frame to said mobile station is CFN and said balance adjustment period is $N_{\text{periodframe}}$, said control step includes a step responsive to reception of said control instruction to perform
20 initiation control of said balance adjustment period from a frame where said CFN becomes $m \times N_{\text{period}} + L$ (wherein m is 0 or natural number and L is 0 or natural number common to all base stations).

[CLAIM 35]

25 A storage medium as set forth in claim 34, wherein said m is natural number and said L is 0.

[CLAIM 36]

A storage medium as set forth in claim 31, wherein
said control step resumes said balance adjustment period
from a frame defined by the same rule as a rule determining
initiation of the balance adjustment period when said frame
5 number is varied from the maximum value to a minimum value
or from the minimum value to the maximum value in
discontinuous manner.

[CLAIM 37]

A storage medium as set forth in claim 31, wherein
10 said control step resumes said balance adjustment period
from a frame defined by the same rule as a rule determining
initiation of the balance adjustment period when said frame
number is varied from the maximum value to a minimum value
or from the minimum value to the maximum value in
15 discontinuous manner.

[CLAIM 38]

A storage medium as set forth in claim 31, wherein
assuming that a frame number of transmission frame to said
mobile station is CFN, said balance adjustment period is
20 Nperiod frame, said control step selects said Nperiod as
a value satisfying a relationship of $k \times N_{\text{period}} = \text{CFN}_{\text{max}}$
(k is integer) when minimum value of said CFN is 1, maximum
value is CFNmax or minimum value is 0 and maximum value is
CFNmax - 1, to initiate control of said balance adjustment
25 period from a frame to be $m \times N_{\text{period}} + L$ (wherein m is 0
or natural number and L is 0 or natural number common to
all base stations).

[CLAIM 39]

A storage medium as set forth in one of claims 31 to 38, wherein said control step sets an adjustment amount in said balance adjustment at a value of predetermined ratio
5 to a difference between said transmission power upon initiation of said balance adjustment period and a reference value.

[CLAIM 40]

A storage medium storing a control program for a
10 transmission power control method in a cellular communication system including a plurality of cells, a plurality of base stations respectively arranged in respective of said plurality of cells, mobile stations moving within said cells, and control station provided in common
15 for said plurality of base stations and transmitting control instruction for balance adjustment of transmission power to respective of said mobile stations from said base stations, each of said base station initiate control of a balance adjustment period from a frame to be $m \times N_{\text{period}} + L$ (wherein
20 m is 0 or natural number and L is 0 or natural number common to all base stations, N_{period} is a period for performing said balance adjustment),

said control program comprising step of selecting said N_{period} as a value satisfying a relationship of $k \times N_{\text{period}} = \text{CFN}_{\text{max}}$ (k is integer) assuming that a frame number of
25 transmission frame to said mobile station is CFN , said balance adjustment period is N_{period} frame, minimum value of said

CFN is 1, maximum value is CFNmax or minimum value is 0 and maximum value is CFNmax - 1.

[DETAILED DESCRIPTION OF THE INVENTION]

[0001]

5 [PRIOR ART]

The present invention relates generally to a transmission power control system, a control method, a base station and a control station and a storage medium recording a control program. More particularly, the invention relates
10 to a method for determining a balance adjustment start timing upon performing balance adjustment of a transmission power for one mobile station from a plurality of base stations at the occurrence of soft hand-over in cellular communication system.

15 [0002]

[PRIOR ART]

In a code division multiplex cellular system, a plurality of channels use the same frequency, a reception power (desired wave power) of a signal at certain channel
20 becomes an interference wave power to be jamming for other channels. Accordingly, in an uplink transmitted from a mobile station to a base station, when the desired wave power is greater than or equal to a predetermined value, interference wave power is increased to reduce capacity of
25 the channel. In order to prevent this, it becomes necessary to strictly control the transmission power of the mobile station. The transmission power control in the uplink is

performed in such a manner that the base station measures the desired wave power to compare with a target control value for transmitting a up control instruction for reducing a transmission power (hereinafter referred to as "up
5 transmission power") of the uplink for the mobile station when the desired power is larger than the target control value, and for transmitting the up control instruction for increasing the up transmission power for the mobile station when the desired wave power is smaller than the target control
10 value. Then, the mobile station increases or decreases the up transmission power according to the up control instruction. Transmission of the up control instruction in the transmission power control is performed using a downlink transmitting from the base station to the mobile station.

15 [0003]

On the other hand, even in the downlink, by performing transmission power control so that a ratio between the desired wave power and the interference wave power becomes a predetermined amount to realize high channel capacity. In
20 greater detail, in the transmission power control in the downlink, the mobile station measures a reception quality of the downlink to compare with a target control value for transmitting a down control instruction for reducing transmission power of the downlink (hereinafter referred
25 to as "down transmission power") for the base station when the reception quality is higher than the target control value, and for transmitting down control instruction for increasing

the down control power when the reception quality is lower than the target control value. Then, the base station increases or decreases the down transmission power according to the down control instruction.

5 [0004]

 However, in this method, when propagation loss from the mobile station to the base station is abruptly increased associating with movement of position of the mobile station, the base station cannot receive the down control instruction
10 from the mobile station. At the same time, even in the mobile station, it can become impossible to receive the up control instruction from the base station. At this time, in the conventional method for only controlling transmission power of the downlink in the mobile station by down control
15 instruction from the base station, when a condition where the propagation loss is increased, is continued, while the base station cannot receive the down control instruction from the mobile station, the base station does not increase the transmission power of the downlink. Therefore, even
20 in the mobile station, it becomes impossible to receive the up control instruction from the base station. Thus, the up transmission power of the signal in the uplink is not increased to continue a condition where communication between the mobile station and the base station is
25 interrupted.

 [0005]

 On the other hand, in general, among signals received

by the base station, a portion of user information, such as voice, data and so forth are encoded in such a manner that information having relatively long data length are encoded in a lump so that they can be accurately decoded
5 by performing error correction and so forth even when reception error in a moment is caused. Even upon decoding, information having long data length can be decoded in a lump over a relatively long period.

[0006]

10 However, during movement of the mobile station at high speed, when high speed transmission power control is performed for maintaining a reception quality constant following to high speed fading fluctuation in the propagation path, even if the user information can be decoded accurately,
15 judgment of the control instruction has to be performed in a moment. Effect of error correction and so forth cannot be obtained in judgment of the control instruction to contain error relatively frequently.

[0007]

20 Since error in judgment of such control instruction is caused in relation to increase and decrease of propagation loss, possibility of continuously causing propagation loss becomes relatively high. Then, when judgment error of the control instruction is continuously caused, the base station
25 cannot control the down transmission power of the signal in the downlink according to the down control instruction from the mobile station to make it impossible to accurately

receive the signal in the downlink in the mobile station. On the other hand, in this condition, even in the mobile station, since the up control instruction from the base station contained in the signal of downlink cannot receive, 5 the up transmission power of the signal in the uplink is also become impossible to control. At this time, in the base station, among signals in uplink, error of judgment of the down control instruction can be caused frequently, and also, it becomes possible that the user information cannot 10 receive accurately. Even in such case, a condition where communication between the base station and the mobile station is interrupted, is continued.

[0008]

On the other hand, in the cellular system, when the 15 mobile station moves between cells, there is a soft hand-over technology for switching channels between the cells with simultaneously setting the channels with a plurality of the base stations in the vicinity of the boundary between the cells. This technology is important in the cellular system 20 employing the code division multiplexing system. Regarding the soft hand-over technology, it is described in detail in the specification of USP.5,102,501.

[0009]

Transmission power control in uplink during execution 25 of soft hand-over is important for enabling reception of all up control instructions of all base stations where the propagation loss in uplink potentially becomes minimum.

[0010]

Therefore, a method for controlling the transmission power of the downlink to equalize the desired wave power from respective base stations in the mobile station, can
5 be considered. However, in this method, since the base station having large propagation loss to the mobile station sets the down transmission power to be large correspondingly to increase interference wave and whereby to reduce capacity of the downlink. As a method for restricting reduction of
10 the capacity of the downlink, there is a method for controlling the down transmission power of respective base stations to be equal to each other.

[0011]

In this method, a reception power of the up control
15 instruction from the base station having small propagation loss to the mobile station is greater than the reception power of the up control instruction from the base station having large propagation loss to the mobile station. When a difference of the propagation losses is large, probability
20 of reception failure of the up control instruction from the base station having large propagation loss becomes high. In such case, the transmission power in the uplink is mainly controlled by up control instruction from the base station having small propagation loss. Therefore, no significant
25 problem will be arisen. On the other hand, when the difference of the propagation losses is small, it is important to control the up transmission power according to both base

stations. In such case, since respective up control instructions can be received at substantially equal power, probability of accurately receiving both up control instructions becomes high. Accordingly, for transmission power control of the uplink, all up control instructions from the base stations which potentially have minimum propagation loss of the uplink can be received.

[0012]

On the other hand, during execution of soft hand-over, when large and small of the propagation loss from the mobile station to respective base stations is switched at high speed due to fading fluctuation or other cause, the base station having the minimum propagation loss performs transmission at any moment even without switching of the base stations to perform transmission to the mobile station at high speed. At this time, unless the down transmission power of the base stations are equal to each other, reception quality can be increased or decreased upon switching of the base station having the minimum propagation loss to easily cause degradation of the reception quality. However, when down transmission power of respective base stations are equal to each other, the reception quality can be maintained substantially constant even when the base stations having the minimum propagation loss is switched to improve reception quality by diversity effect.

[0013]

In such transmission power control in downlink, the

mobile station measures the reception quality of the downlink to compare with the target control value to transmit the down control instruction for reducing the down transmission power for the base station when the reception quality is higher than the target control value, and to transmit the down control instruction for increasing the down transmission power for the base station when the reception quality is lower than the target control value. During execution of soft hand-over, the down control instruction transmitted from the mobile station is received by a plurality of base stations. Then, respective base stations controls the down transmission power to increase or decrease according to the down control instruction. Accordingly, if the initial values of the down transmission power of respective base stations are mutually equal to each other, similar increase or decrease is repeated. If no error is contained in reception of down control instruction, down transmission power can be controlled with maintaining equal condition.

[0014]

However, in this method, in the base station where the propagation loss to the mobile station becomes minimum, down control instruction from the mobile station can be received in substantially accurate. However, in the base station having relatively large propagation loss in transmission from the mobile station, reception of down control instruction from the mobile station can be frequently failed for small transmission power of the down control

instruction. Accordingly, it becomes impossible maintain the down transmission powers of respective base stations equal to each other.

[0015]

5 Therefore, during execution of the soft hand-over, a transmission power control method in the cellular communication system, in which substantially equal power can be transmitted from respective each base station even if error is caused in reception of the down control
10 instruction in respective base stations, and whereby high channel capacity can be attained, has been proposed in Japanese Unexamined Patent Publication No. Heisei 11-340910.

[0016]

15 Fig. 6 schematically shows the construction of the cellular communication system. In Fig. 6, service area is divided into first and second cells 11 and 12. In the first and second cells 11 and 12, first and second base stations (#1) 21 and (#2) 22 are respectively arranged. Also, first
20 and second mobile stations 61 and 62 are present in the first and second cells 11 and 12. The first and second base stations 21 and 22 are connected to a common control station 71. The common control station 71 is connected to a communication network (not shown) constituted of other control station.
25 It should be noted that while not illustrated, the cellular communication system includes other large number of base stations, and in each cell, large number of mobile stations

are present.

[0017]

The first and second base stations 21 and 22 transmit first and second pilot signals 31 and 32 at respectively given transmission power. Each mobile station 61, 62 has SIR (a ratio of desired wave and an interference power) measuring equipment for measuring a power of the pilot signal for respectively measuring reception power of the first and second pilot signals 31 and 32. The mobile station switches the measuring equipment of the pilot signal in a short period per slot (time slot) as shown in Fig. 7 and measures the pilot signals of a plurality of base station once per frame. In the example of Fig. 7, six slots are present within one frame and permit measurement of the pilot signals from the six base stations at the maximum. In Fig. 6, the reference numerals 41, 41a, 41b, 42 denote signals in downlink and 51, 52 denote signals in uplink.

[0018]

Next, discussion will be given for the transmission power control for downlink in the cellular communication system shown in Fig. 6 with reference to Fig. 8. Fig. 8 is a flowchart showing operation of the base station for determining the down transmission power in the downlink in response to the down control instruction from the mobile station during soft hand-over. Here, the down transmission power P is expressed by a decibel value.

[0019]

When the base station initiates soft hand-over with the mobile station, if the base station in question is the primary base station which has been transmitting to the mobile station before, the down transmission power P maintains the preceding value of the transmission power to the mobile station. On the other hand, if the base station is an auxiliary base station newly starting transmission to the mobile station, the down transmission power P is set at an initial value P_0 . The primary station and the auxiliary station are notified a frame number to initiate soft hand-over from the control station 71. The initial value P_0 may be an arbitrary value falling within a control range of the down transmission power.

[0020]

At first, when a transmission power balance control message between a plurality of base stations arrives from the control station 71, the base station resets a frame counter $I = 0$ (step S201). The frame counter I is incremented by 1 per frame (step S202). Here, the down control instruction (TPC: Transmission Power Control) is notified from the mobile station at a given interval. When the newly notified down control instruction is present (step S203) and the down control instruction designates increasing of the power (step S204), the down transmission power P is increased for a predetermined value ΔP (step S205), and when the down control instruction designates decreasing of the power, the transmission power P in the downlink is

decreased for the predetermined value ΔP (step S206).

[0021]

The foregoing processes S203 to S206 are repeated for frame number Nperiod as a predetermined balance adjusting period. After expiration of the predetermined balance adjusting period (step S207), namely when $I = N\text{period}$ is established, a difference $(C - P)$ between a predetermined reference power (referred to as target value or reference value) C and the down transmission power P before updating, is multiplied with a coefficient $(1 - r)$ to integrate the down transmission power P (step S208).

$$P = P + (1 - r) (C - P)$$

The coefficient r is a predetermined value within a range greater than or equal to 0 and less than 1. On the other hand, C is an intermediate power between the maximum power P_{max} and the minimum power P_{min} of the transmission power P .

[0022]

If the updated transmission power is greater than the maximum power P_{max} , the down transmission power P is set at the maximum power P_{max} (steps S209, S210). When the updated transmission power P is smaller than the minimum power P_{min} , the down transmission power P is set at the minimum power P_{min} (steps S211, S212). Then, the process is repeated from the step S202.

[0023]

In this method, upon timing of initiation of the soft hand-over, since the initial values of the down transmission power of the primary base station and the auxiliary base station are different, there is a difference $|P1 - P2|$ between the down transmission power $P1$ of the primary base station and the down transmission power $P2$ of the auxiliary base station. On the other hand, upon failure of reception of the down control instruction in one or more base stations, the difference $|P1 - P2|$ of these transmission powers $P1$ and $P2$ can be increased. However, in a portion of control through steps S203 to S206, namely a portion for increasing and decreasing the down transmission power by the down control instruction from the mobile station, respective base stations receive the same down control instruction. Therefore, respective base stations do not fail reception of the down control instruction, the down transmission power $P1$ and $P2$ are increased or decreased in similar manner so as not to vary the difference $|P1 - P2|$ of these down transmission powers $P1$ and $P2$.

[0024]

On the other hand, at the same time, per frame number of $I = N_{\text{period}}$, the primary base station and the auxiliary base station simultaneously update the down transmission powers $P1$ and $P2$ as $P1 + (1 - r)(C - P1)$, $P2 + (1 - r)(C - P2)$. Therefore, the difference $|P1 - P2|$ of the down transmission powers $P1$ and $P2$ becomes $r|P1 - P2|$. Thus,

the difference $|P_1 - P_2|$ of the down transmission power becomes r times per the period N_{period} . Since the coefficient r is smaller than 1, the difference of the control amount is decreased in geometric manner to be converged to
5 0 unless the difference $|P_1 - P_2|$ of the down transmission powers is increased due to reception error of the new down control instruction. On the other hand, even if the difference $|P_1 - P_2|$ of the down transmission power is increased due to occurrence of reception error of the new
10 down control instruction, the difference $|P_1 - P_2|$ can be decreased. Accordingly, even by failure of reception of the down control instruction, the transmission powers P_i ($i = 1, 2$) in the downlink can be adjusted to substantially equal value between the base stations without direct exchange
15 of information concerning the down transmission power between the base stations.

[0025]

Namely, after increasing or decreasing the down transmission power by the control at steps S203 to S206,
20 the difference of the down transmission power of a plurality of base stations can be decreased (balance adjustment), and thus the down transmission power is updated to be closer to the reference power C determined in common for a plurality of base stations.

25 [0026]

As set forth above, during execution of the soft hand-over by the mobile station, up control instruction of

the transmission power control of the uplink is transmitted at substantially equal power between the base stations from each base station to the mobile station. Therefore, when the propagation losses from respective base stations to the mobile stations are substantially the same, when the propagation loss in the uplink can be minimum in any base station. all up control instructions can be received in the mobile station. Accordingly, the mobile station can control the up transmission power so that the desired wave power will not become excessive for any base station.

On the other hand, during execution of the soft hand-over, even if large and small relationship of the propagation losses from the mobile station and respective base stations is switched at high speed due to fading fluctuation or the like, owing to diversity effect to maintain the reception quality substantially constant, the reception quality in the mobile station can be further improved. By controlling the up transmission power so that the desired wave power will not become excessive, channel capacity of the uplink can be increased. On the other hand, if the reception quality in the mobile station can be improved by diversity effect, the channel capacity of the downlink at constant reception quality, can be increased.

[0027]

[PROBLEM TO BE SOLVED BY THE INVENTION]

As set forth above, in each base station, the transmission power is decreased for an adjusting amount in

the balance adjusting period for the transmission power. The adjusting amount is derived as a predetermined ratio of the difference between the transmission power at starting timing of the adjusting period and the reference value C.

5 This manner is illustrated in Fig. 9(a). In the drawing of Fig. 9, P_{bali} ($i = 1, 2$) is the power amount to be adjusted, and $T1$, $T2$ and $T3$ are adjusting timings. It should be noted that the drawing shows the width of P_{bali} with taking $r = 0$.

10 [0028]

Since the transmission power in each base station is increased or decreased according to the same transmission power control instruction (TPC bit) from the mobile station, if reception error is not contained in the transmission power control instruction, the transmission power of the base station can be increased or decreased in similar manner. At this time, if the start timing of the adjusting period is the same timing at respective base stations, when the transmission power of one of two base stations is large ($P1 > P2$), the difference P_{bal} between the transmission power at the start timing of the adjusting period and the reference value C is also large in comparison with that of other base station ($P_{bal1} > P_{bal2}$), the transmission power ($P1$) of one of two base stations is decreased significantly during the adjusting period. As set forth, the base station having large transmission power is significantly decreased the transmission power to reduce the difference of the

15
20
25

transmission power between the base stations to effect balance adjustment.

[0029]

However, as shown in Fig. 9(b), when the start timing
5 of the adjusting period is difference between the base
stations such as T_1 and T_1' , since the transmission power
according to the transmission power control instruction is
constantly varied, if the transmission power of one of two
base stations becomes greater than the other base station
10 ($P_1 > P_2$), the adjustment start timing T_1 of the former base
station is a moment where the transmission power is relatively
small, and the adjustment start timing of later base station
is a moment where the transmission power is relatively large,
the difference between the transmission power at start timing
15 of the adjusting period and the reference C becomes large
in the later base station than the former base station (P_{bal1}
< P_{bal2}) to significantly reduce the transmission power of
the adjusting period. Therefore, the difference of the
transmission powers of the base stations becomes large to
20 cause difficulty in establishing balance of the power. As
a result, equalization of the transmission powers between
the base stations cannot be achieved to decrease channel
capacity.

[0030]

25 As set forth above, the phenomenon where the start
timings of the adjusting periods are different such as T_1
and T_1' , is caused by the fluctuation of arrival timings

of the control messages for transmission power balance adjustment to respective base stations 21 and 22 from the control station 71 due to fluctuation of transmission delay between the control station and the base station. The reception timings of the control messages for conventional power balance adjustment shown in Fig. 2(a) is shown in the case where the reception timings are different between the base stations. In Fig. 2(a), Nperiod = 2 is taken as balance adjusting period and eight frame number of 0 to 7 are taken to repeat. As set forth above, in the prior art, a difference of the reception timings of the power balance control messages is constantly continued subsequently. Therefore, calculation timings of Pbal between the base stations are shifted constantly. As shown in Fig. 9(b), reversal of Pbal1 and Pbal2 can be caused.

[0031]

It is an object of the present invention to provide a transmission power control system, a method therefor, a base station and a control station, and a storage medium recording a control program therefor, which can establish synchronization by matching adjustment start timings while repeating adjustment periods even when start timings of transmission power balance adjustment are different due to fluctuation of transmission delay of control message from the control station to base station, and can increase circuit capacity by establishing balance of transmission powers between the base stations.

【0032】

【MEANS FOR SOLVING THE PROBLEM】

According to the aspect of the present invention, a transmission power control system in a cellular communication system including a plurality of cells, a plurality of base stations respectively arranged in
5 respective of the plurality of cells, mobile stations moving within the cells, and control station provided in common for the plurality of base stations and transmitting control
10 instruction for balance adjustment of transmission power to respective of the mobile stations from the base stations,

wherein the base station comprises control means for controlling initiation of a balance adjustment period for performing the balance adjustment from a frame number
15 determined on the basis of frame number of the balance adjustment period.

In the preferred construction, assuming that a frame number of transmission frame to the mobile station is CFN and the balance adjustment period is Nperiod frame, the
20 control means is in responsive to reception of the control instruction to perform initiation control of the balance adjustment period from the frame of the frame number CFN to be mod (CFN, $m \times N_{period}$) = L (wherein, m is natural number, L is 0 or natural number smaller than $m \times N_{period}$ common
25 to all base stations).

【0033】

On the other hand, assuming that a frame number of

transmission frame to the mobile station is CFN and the balance adjustment period is $N_{\text{period}} \text{ frame}$, the control means is responsive to reception of the control instruction to perform initiation control of the balance adjustment period
5 from a frame where a number at the first digit as expressing the CFN by $m \times N_{\text{period}}$ base number (wherein, m is natural number) becomes a predetermined value.

【0034】

Furthermore, assuming that a frame number of
10 transmission frame to the mobile station is CFN and the balance adjustment period is $N_{\text{period}} \text{ frame}$, the control means is responsive to reception of the control instruction to perform initiation control of the balance adjustment period from a frame where the CFN becomes $m \times N_{\text{period}} + L$ (wherein
15 m is 0 or natural number and L is 0 or natural number common to all base stations.

【0035】

Furthermore, assuming that a frame number of
20 transmission frame to the mobile station is CFN and the balance adjustment period is $N_{\text{period}} \text{ frame}$, the control means is responsive to reception of the control instruction to perform initiation control of the balance adjustment period from a frame where the CFN becomes $m \times N_{\text{period}} + L$ (wherein
 m is 0 or natural number and L is 0 or natural number common
25 to all base stations.

【0036】

Also, the control station may include means for

selecting the N_{period} as a value satisfying a relationship of $k \times N_{period} = CFN_{max}$ (k is integer) assuming that a frame number of transmission frame to the mobile station is CFN , the balance adjustment period is $N_{period} \text{ frame}$, minimum value of the CFN is 1, maximum value is CFN_{max} or minimum value is 0 and maximum value is $CFN_{max} - 1$, and

control means of each of the base station may initiate control of the balance adjustment period from a frame to be $m \times N_{period} + L$ (wherein m is 0 or natural number and L is 0 or natural number common to all base stations).

【0037】

Also, assuming that a frame number of transmission frame to the mobile station is CFN , the balance adjustment period is $N_{period} \text{ frame}$, the control means selects the N_{period} as a value satisfying a relationship of $k \times N_{period} = CFN_{max}$ (k is integer) when minimum value of the CFN is 1, maximum value is CFN_{max} or minimum value is 0 and maximum value is $CFN_{max} - 1$, to initiate control of the balance adjustment period from a frame to be $m \times N_{period} + L$ (wherein m is 0 or natural number and L is 0 or natural number common to all base stations). The control means may set an adjustment amount in the balance adjustment at a value of predetermined ratio to a difference between the transmission power upon initiation of the balance adjustment period and a reference value.

【0038】

According to the aspect of the present invention, a

transmission power control method in a cellular communication system including a plurality of cells, a plurality of base stations respectively arranged in respective of the plurality of cells, mobile stations moving
5 within the cells, and control station provided in common for the plurality of base stations and transmitting control instruction for balance adjustment of transmission power to respective of the mobile stations from the base stations,

wherein the method comprises a control step of
10 controlling initiation of a balance adjustment period for performing the balance adjustment from a frame number determined on the basis of frame number of the balance adjustment period, in each base station.

【0039】

15 Then, assuming that a frame number of transmission frame to the mobile station is CFN and the balance adjustment period is Nperiod frame, the control step includes a step of initiating control of the balance adjustment period from the frame of the frame number CFN to be mod (CFN, $m \times Nperiod$)
20 = L (wherein, m is natural number, L is or natural number smaller than $m \times Nperiod$ common to all base stations) in response to reception of the control instruction.

【0040】

Also, assuming that a frame number of transmission
25 frame to the mobile station is CFN and the balance adjustment period is Nperiod frame, the control step is responsive to reception of the control instruction to perform initiation

control of the balance adjustment period from a frame where a number at the first digit as expressing the CFN by $m \times N_{\text{period}}$ base number (wherein, m is natural number) becomes a predetermined value.

5 **【0041】**

Furthermore, assuming that a frame number of transmission frame to the mobile station is CFN and the balance adjustment period is N_{period} frame, the control step includes a step responsive to reception of the control
10 instruction to perform initiation control of the balance adjustment period from a frame where the CFN becomes $m \times N_{\text{period}} + L$ (wherein m is 0 or natural number and L is 0 or natural number common to all base stations).

【0042】

15 The control station performs a step of selecting the N_{period} as a value satisfying a relationship of $k \times N_{\text{period}} = \text{CFN}_{\text{max}}$ (k is integer) assuming that a frame number of transmission frame to the mobile station is CFN, the balance adjustment period is N_{period} frame, minimum value of the
20 CFN is 1, maximum value is CFN_{max} or minimum value is 0 and maximum value is $\text{CFN}_{\text{max}} - 1$, and

control step in each of the base station initiate control of the balance adjustment period from a frame to be $m \times N_{\text{period}} + L$ (wherein m is 0 or natural number and
25 L is 0 or natural number common to all base stations).

【0043】

On the other hand, assuming that a frame number of

transmission frame to the mobile station is CFN, the balance adjustment period is Nperiod frame, the control step selects the Nperiod as a value satisfying a relationship of $k \times \text{Nperiod} = \text{CFNmax}$ (k is integer) when minimum value of the CFN is 1, maximum value is CFNmax or minimum value is 0 and maximum value is CFNmax - 1, to initiate control of the balance adjustment period from a frame to be $m \times \text{Nperiod} + L$ (wherein m is 0 or natural number and L is 0 or natural number common to all base stations). The control step sets an adjustment amount in the balance adjustment at a value of predetermined ratio to a difference between the transmission power upon initiation of the balance adjustment period and a reference value.

【0044】

Also, assuming that the CFN is incremented by one in every frame to be reset to 0 when the CFN exceeds a predetermined number, the control step is responsive to reception of the control instruction to control the balance adjustment starting at a frame with CFN modulo Nperiod equal to 0, and repeating for every Nperiod frame, and restarting at a frame with CFN=0.

【0045】

According to the aspect of the present invention, a base station in a cellular communication system including a plurality of cells, a plurality of the base stations respectively arranged in respective of the plurality of cells, mobile stations moving within the cells, and control station

provided in common for the plurality of base stations and transmitting control instruction for balance adjustment of transmission power to respective of the mobile stations from the base stations, the base station comprises:

5 control means for controlling initiation of a balance adjustment period for performing the balance adjustment from a frame number determined on the basis of frame number of the balance adjustment period.

【0046】

10 Also, assuming that a frame number of transmission frame to the mobile station is CFN and the balance adjustment period is Nperiod frame, the control means initiation control of the balance adjustment period from the frame of the frame number CFN to be $\text{mod}(\text{CFN}, m \times \text{Nperiod}) = L$ (wherein, m is
15 natural number, L is or natural number smaller than $m \times \text{Nperiod}$ common to all base stations).

【0047】

 Furthermore, assuming that a frame number of transmission frame to the mobile station is CFN and the
20 balance adjustment period is Nperiod frame, the control means is responsive to reception of the control instruction to perform initiation control of the balance adjustment period from a frame where a number at the first digit as expressing the CFN by $m \times \text{Nperiod}$ base number (wherein, m is natural
25 number) becomes a predetermined value.

【0048】

 Furthermore, assuming that a frame number of

transmission frame to the mobile station is CFN and the balance adjustment period is Nperiod frame, the control means is responsive to reception of the control instruction to perform initiation control of the balance adjustment period
5 from a frame where the CFN becomes $m \times Nperiod + L$ (wherein m is 0 or natural number and L is 0 or natural number common to all base stations).

【0049】

Assuming that a frame number of transmission frame
10 to the mobile station is CFN and the balance adjustment period is Nperiod frame, the control means resumes the balance adjustment period from a frame to be $m \times Nperiod + L$ when the frame number is varied from the maximum value to a minimum value or from the minimum value to the maximum value in
15 discontinuous manner.

【0050】

Also, assuming that a frame number of transmission frame to the mobile station is CFN, the balance adjustment period is Nperiod frame, the control means selects the Nperiod
20 as a value satisfying a relationship of $k \times Nperiod = CFNmax$ (k is integer) when minimum value of the CFN is 1, maximum value is CFNmax or minimum value is 0 and maximum value is CFNmax, to initiate control of the balance adjustment period from a frame to be $m \times Nperiod + L$ (wherein m is 0 or natural
25 number and L is 0 or natural number common to all base stations). The control means sets an adjustment amount in the balance adjustment at a value of predetermined ratio to a difference

between the transmission power upon initiation of the balance adjustment period and a reference value.

【0051】

According to the aspect of the invention, a control
5 station in a cellular communication system including a
plurality of cells, a plurality of base stations respectively
arranged in respective of the plurality of cells, mobile
stations moving within the cells, and control station
provided in common for the plurality of base stations and
10 transmitting control instruction for balance adjustment of
transmission power to respective of the mobile stations from
the base stations, each of the base station initiate control
of a balance adjustment period from a frame to be $m \times N_{period}$
+ L (wherein m is 0 or natural number and L is 0 or natural
15 number common to all base stations, N_{period} is a period for
performing the balance adjustment),

the control station comprising means for selecting
the N_{period} as a value satisfying a relationship of $k \times N_{period}$
= CFNmax (k is integer) assuming that a frame number of
20 transmission frame to the mobile station is CFN, the balance
adjustment period is N_{period} frame, minimum value of the
CFN is 1, maximum value is CFNmax or minimum value is 0 and
maximum value is CFNmax - 1.

【0052】

25 According to the aspect of the present invention, a
storage medium storing a transmission power control method
in a cellular communication system including a plurality

of cells, a plurality of base stations respectively arranged
in respective of the plurality of cells, mobile stations
moving within the cells, and control station provided in
common for the plurality of base stations and transmitting
5 control instruction for balance adjustment of transmission
power to respective of the mobile stations from the base
stations,

wherein the control program comprises a control step
of controlling initiation of a balance adjustment period
10 for performing the balance adjustment from a frame number
determined on the basis of frame number of the balance
adjustment period, in each base station.

[0053]

In the operation, upon soft hand-over of certain mobile
15 station with a plurality of base stations, when balance
adjustment of the transmission power from a plurality of
base stations to the mobile station, balance adjustment
period for performing balance adjustment in each base station
is initiated at the frame number determined on the basis
20 of number of frames in the balance adjustment period. By
this, even when the reception timing of the balance control
message from the control station is shifted due to fluctuation
of transmission delay, synchronization of balance
calculation timing for balance adjustment can be established
25 between the base stations during repletion of balance
adjustment period to enable accurate balance of the
transmission power between the base stations.

On the other hand, when the balance control message is received in each base station before and after discontinuous variation of the frame number of the transmission frames from the maximum value to the minimum value (or from the minimum value to the maximum value), timing of balance adjustment can be shifted due to relationship between the period of the balance adjustment and total number of frames. However, by resuming balance adjustment period from the frame defined by the same rule as the rule determining the frame initiating the balance adjustment period, the frame number to be candidate of initiation of the balance adjustment period is held unchanged even when the frame number is repeated returning from the maximum value to the minimum value. Accordingly, synchronization is established between the base stations in the balance calculation timing, balance of transmission power can be accurately established between the base stations.

On the other hand, a frame number of transmission frame to the mobile station is CFN, the balance adjustment period is N_{period} frame, by selecting the N_{period} as a value satisfying a relationship of $k \times N_{period} = CFN_{max}$ (k is integer), the frame number to be candidate of initiation of the balance adjustment period is held unchanged even when the balance control message is received in each base station before and after discontinuous variation of the frame number of the transmission frames from the maximum value to the minimum value (or from the minimum value to the maximum value).

Accordingly, synchronization is established between the base stations in the balance calculation timing, balance of transmission power can be accurately established between the base stations.

5 [0054]

 [DESCRIPTION OF THE PREFERRED EMBODIMENT]

 The present invention will be discussed hereinafter in detail in terms of the preferred embodiment of the present invention with reference to the accompanying drawings. Fig.
10 1 is a schematic block diagram showing a construction of the preferred embodiment of a base station according to the present invention. It should be noted that a system construction is the same as that illustrated in Fig. 6. On the other hand, a frame structure of downlink from the first
15 and second base stations (#1) 21 and (#2) 22 to the mobile station 51 is the same as the example shown in Fig. 7. Between the base stations, frame number to be transmitted at the same time is the same.

 [0055]

20 Referring to Fig. 1, the base station includes an antenna 201, a transmission and reception common portion 202, a reception circuit 203 performing reception process of a received signal and outputting the received signal to a terminal 207, a SIR measuring portion 204 performing SIR
25 measurement of downlink, a transmission power control portion 205 performing control of a transmission power with reference to the result of SIR measurement or the like, and

a transmission circuit 206 superimposing transmitting signal from a terminal 208 and SIR measurement result signal and controlling amplification depending upon control from the transmission power control portion 205. On the other hand, in order to perform operation control for respective portions, CPU (control unit) 209 and read-only storage medium (ROM) 210 preliminarily storing program for operation control of CPU are included.

[0056]

The present invention prevents occurrence of the transmission powers of the base stations falling out of balance for increasing of difference therebetween due to shifting of timings, such as $T1$ and $T1'$ of the power balance control messages from the control station 71 at the first base station #1 and the second base station #2, as shown in Fig. 9(b). Therefore, as shown in Fig. 2(b), the adjustment start timings of power balance between the base stations become the same to establish synchronization with each other.

[0057]

In the example shown in Fig. 2(b), there is shown an example where the message is consisted of eight frames of frame numbers CFN of 0 to 7 (total number of the frame (number) is CFN_{max} , $CFN_{max} - 1 = 7$), the message of eight frames is repeated, and the adjusting period is set as $N_{period} = 2$.

[0058]

Generally expressing, three modes are considered. At

first, in the first mode, balance adjustment period is controlled to start at a frame of the frame number CFN which is expressed by:

5 $\text{mod} (\text{CFN}, m \times \text{Nperiod}) = L$

wherein m is natural number, L is 0 or natural number smaller than Nperiod and common to all base stations. Namely, at the frame of the frame number to have remainder "L" as dividing CFN by $(m \times \text{Nperiod})$, balance adjustment is initiated. Subsequently, balance adjustment is performed at every Nperiod . In the example of Fig. 2(b), it corresponds to $m = 1$ and $L = 0$. In FIG. 2, a calculation timing of P_{bal} is shown as leading end of the frame. However, in practice, the P_{bal} calculation timing may be a predetermined timing (e.g. (S)th slot) of the frame.

[0059]

As second mode, when the frame number CFN is expressed by $m \times \text{Nperiod}$ base number (m is natural number), balance adjustment is initiated from the frame where the number of the first digit becomes a predetermined value. Subsequently, balance adjustment is performed at every Nperiod . In the example shown in Fig. 2(b), this corresponds to the case where $m = 1$ and the predetermined value = 0.

25 [0060]

As the third mode, the balance adjustment is initiated from the frame where the frame number CFN becomes $m \times \text{Nperiod}$

+ L, wherein m is 0 or natural number and L is 0 or natural number common to all base stations. In the example shown in Fig. 2(b), this corresponds to the case where $m = 1$ and $L = 0$.

5 [0061]

Fig. 3 is a flowchart showing operation of the base station in the foregoing respective modes. In response to arrival (reception) of the power balance control message from the control station, the control operation shown in
10 Fig. 3 is initiated. At first, a current frame number CFN is obtained (step S11), and a frame counter (not particularly shown) I is set at $I = \text{mod}(\text{CFN}, N_{\text{period}})$ (step S12). Then, $P_{\text{bal}} = (1 - r)(C - P)$ shown in Fig. 9 is reset to 0 (step S13). It should be noted that Fig. 9 is illustrated as a
15 level where the reference value C becomes smaller than the transmission powers P1 and P2 of respective base stations. In such case, it becomes $P_{\text{bal}} = (1 - r)(P - C)$. However, in the shown embodiment discussion will be shown in the case where the reference value C is set to be greater than the
20 transmission powers P1 and P2 of respective base stations.

[0062]

Next, a slot counter (not particularly illustrated) J is reset to $J = 0$ (step S14). Then, the system is placed in waiting state for TPC bit (step S15). In response to
25 reception of the TPC bit, when the TPC bit is power increasing instruction (step S16), the transmission power P is controlled to increase for a predetermined amount S1 (step

S17). Conversely, when the TPC bit is power decreasing instruction, the transmission power P is controlled to decrease for the predetermined amount $S1$ (step S18). When P_{bal} is greater than a predetermined value $S2$ (step S19),
5 the transmission power P is controlled to increase for the predetermined amount $S2$ (step S20) and P_{bal} is controlled to decrease for the predetermined amount $S2$ (step S21).
[0063]

At step S19, when P_{bal} is smaller than the predetermined
10 amount $S2$, comparison of P_{bal} and $-S2$ is performed (step S22). If P_{bal} is smaller than $-S2$, a process of $P - S2$ is performed (step S23), and in conjunction therewith, P_{bal} is controlled to increase for the predetermined amount $S2$ (step S24). After steps S21 and S24 or when answer at step
15 S22 is "NO", the slot counter is incremented by 1 (step S25).
[0064]

The foregoing process of steps S15 to S25 is repeated for number of slots N_{slot} consisting one frame (step S26). By repeating for N_{slot} times to be $J = N_{slot}$, the frame counter
20 I is incremented by 1. Then, process transit to the process for the next frame (step S28). At this time, until I becomes equal to N_{period} , the process through foregoing steps S14 to S27 is repeated.

[0065]

25 When $I = N_{period}$ is established, adjustment of P_{bal} is initiated. Namely, $P_{bal} = (1 - r) (C - P)$ is calculated (step S29), and resetting of the frame counter $I = 0$ is

performed (step S30). Then, process is returned to step S14 against start transmission power control from the first slot $J = 0$ in the next frame.

[0066]

5 Through the foregoing process, control of the transmission power of respective base stations in downlink is performed by the TPC bit in each slot, and in conjunction therewith, synchronization of initiation timing of power balance between the base stations is established with
10 compensating error of initiation timing due to fluctuation caused by transmission delay of the power balance control message from the control station.

[0067]

Operational flowchart shown in Fig. 3 is a flowchart
15 which can be established only when CFNmax is integer multiple of N period in the case where the frame number CFN is 0 to maximum value (CFNmax - 1) and total frame number is repeated in CFNmax. However, when CFNmax is not integer multiple of Nperiod, for example, as shown in Fig. 4, calculation
20 timing of Pbal of the base station #1 is executed per Nperiod = 3 after initiation from the frame number CFN = 4. In the next frames of 0 to 7, the frame number CFN = 2 becomes the calculation timing. At this time, when arrival timing of the power balance control message to the base station #2
25 is the frame number CFN = 1, calculation timing of Pbal becomes the frame number CFN = 4. Then, synchronization of calculation timings of both base stations cannot be

established to cause a problem.

[0068]

Therefore, in such case, in the base station #1, the frame number CFN is reset to "0" to restart calculation timing from the frame number of $m \times N_{\text{period}} + L$ (m is 0 or natural number, L is 0 or natural number common to all base stations) for establishing synchronization between the base stations #1 and #2. It should be noted that, in the example of Fig. 4, $m = 0$ and $L = 1$.

As set forth above, the frame number is varied from the maximum value to the minimum value (or from the minimum value to the maximum value) in discontinuous manner, synchronization can be established by restarting the balance control period from the frame determined by the same rule as the rule determining the frame starting the balance adjustment period.

[0069]

In such case, operational flowchart of the base station is shown in Fig. 5. In the flowchart shown in Fig. 5, the same or equivalent steps with the flowchart shown in Fig. 3 are shown by the same reference numerals and redundant discussion for such common steps will be eliminated for avoiding redundancy of disclosure and whereby for maintaining the disclosure simple enough to facilitate clear understanding of the present invention. Therefore, the following discussion will be given mainly for portions different from Fig. 3. Next to step S27, a frame number

counter CFN is provided and is incremented by 1 (step S31). Then, the value of the frame number counter is checked whether it becomes the maximum value CFNmax or not (step S32). If the result of checking is "YES", the frame number counter
5 CFN is reset to "0" (step S33). The, process is returned to step S29.

[0070]

In the discussion for Figs. 4 and 5, there is shown the case where value of the frame number counter is ascending
10 order, the same is applicable for the case of descending order.

[0071]

In Fig. 5, Pbal is calculated based on the power value P at the end of the frame per Nperiod frame including CFN
15 = 0. On the other hand, in the flowcharts shown in Figs. 3 and 5, Pbal is calculated as $P_{bal} = (1 - r) (C - P)$ for updating Pbal per calculation. However, it may be an example for integration as $P_{bal} = P_{bal} + (1 - r) (C - P)$.

[0072]

20 By selecting a value where an integer k to establish $k \times N_{period} = CFN_{max}$ as Nperiod, the embodiment resetting the foregoing frame number counter CFN to "0" becomes unnecessary, as a matter of course. In this case, selecting Nperiod at a value at which an integer k satisfying $k \times N_{period}$
25 = CFNmax, is present, may be performed by the base station. However, such selection is typically done by the control station and is noticed to each base station. Accordingly,

in each base station, by starting balance adjustment at the frame to be $m \times N_{\text{period}} + L$, synchronization of calculation timing in both base station can be established even when the frame number CFN is varied from the maximum value to the minimum value (or conversely returning from the minimum value to the maximum value for counting down). For example when $CFN_{\text{max}} = 256$, N_{period} is selected among 1, 2, 4, 8, 16, 32, 64, 128 and 256.

[0073]

On the other hand, concerning operational flowchart of Figs. 3 and 5, the process is executed by CPU 209 which reads out the program stored in the storage medium, such as ROM 210 shown in Fig. 1. While not particularly illustrated, concerning functional block diagram and operational flowchart in the control station, by preliminarily storing operation control program in the storage medium, CPU may read out the program for execution to perform operation of transmission of the transmission power balance control message and selected.

[0074]

[EFFECT OF THE INVENTION]

As set forth above, according to the present invention, when reception timings of the control signal are different due to fluctuation of transmission delay of the control signal from the control station to the base station, even though starting points of the first adjusting period are different, timing of subsequent balance adjustment is synchronized.

By this, balance of the transmission power between the base stations can be improved to contribute for increasing of channel capacity.

[0075]

5 Particularly, in the invention performing resumption control, synchronization of timing of balance adjustment can be established even when a value where k satisfying $k \times \text{CFNmax}$ does not present is selected as N_{period} . Therefore, N_{period} can be selected irrespective of the value of CFNmax .
10 Therefore, in order to satisfy predetermined demanded reference for balancing the transmission power between the base stations, frequency of balance adjustment has to be greater than or equal to a predetermined frequency. However, since N_{period} can be selected irrespective of the value of
15 CFNmax , frequency of balance adjustment can be made greater than or equal to the predetermined frequency but minimum. Therefore, process of control for establishing synchronization of timing of balance adjustment can be reduced.

20 [0076]

 On the other hand, in the present invention for selecting the value where k satisfying $k \times N_{\text{period}} = \text{CFNmax}$, as N_{period} , resumption control becomes unnecessary even when total number of frames is limited. Therefore, process of
25 control for establishing synchronization of timing of balance adjustment can be reduced.

[NAME OF DOCUMENT] ABSTRACT

[ABSTRACT]

[PROBLEM]

In cellular communication system, when reception
5 timings of transmission power balance control signals are
different due to fluctuation of transmission delay of control
signals from a control station to base stations, the present
invention establishes synchronization of balance
adjustments to establish balance of transmission powers
10 between the base stations.

[MEANS FOR SOLVING THE PROBLEM]

Assuming that a frame number of transmission frame
to a mobile station is CFN and a balance adjustment period
is N_{period} frame, control of the balance adjustment period
15 is initiated from a frame where the CFN becomes $\text{mod}(\text{CFN},$
 $m \times N_{period}) = L$ 'wherein m is natural number and L is 0 or
natural number smaller than $m \times N_{period}$ common to all base
stations), in response to reception of the control signal.
By this, timings of the subsequent balance adjustments are
20 synchronized and balance of the transmission powers between
the base stations can be improved.
